MAKING OPEN SOURCE MORE INCLUSIVE

Red Hat is committed to replacing problematic language in our code, documentation, and web properties. We are beginning with these four terms: master, slave, blacklist, and whitelist. Because of the enormity of this endeavor, these changes will be implemented gradually over several upcoming releases. For more details, see [our CTO Chris Wright's message](#).

PROVIDING FEEDBACK ON RED HAT DOCUMENTATION

We appreciate your input on our documentation. Tell us how we can make it better.

Providing documentation feedback in Jira

Use the [Create Issue](#) form to provide feedback on the documentation. The Jira issue will be created in the Red Hat OpenStack Platform Jira project, where you can track the progress of your feedback.

1. Ensure that you are logged in to Jira. If you do not have a Jira account, create an account to submit feedback.
2. Click the following link to open a the **Create Issue** page: [Create Issue](#)
3. Complete the **Summary** and **Description** fields. In the **Description** field, include the documentation URL, chapter or section number, and a detailed description of the issue. Do not modify any other fields in the form.
4. Click **Create**.

CHAPTER 1. INTRODUCTION TO RED HAT OPENSTACK PLATFORM MONITORING TOOLS

Monitoring tools are an optional suite of tools designed to help operators maintain an OpenStack environment. The tools perform the following functions:

- **Centralized logging:** Allows you gather logs from all components in the OpenStack environment in one central location. You can identify problems across all nodes and services, and optionally, export the log data to Red Hat for assistance in diagnosing problems.
- **Availability monitoring:** Allows you to monitor all components in the OpenStack environment and determine if any components are currently experiencing outages or are otherwise not functional. You can also configure the system to alert you when problems are identified.

1.1. SUPPORT STATUS OF MONITORING COMPONENTS

Use this table to view the support status of monitoring components in Red Hat OpenStack Platform (RHOSP).

Table 1.1. Support status

Component	Fully supported since	Deprecated in	Removed since	Note
Aodh	RHOSP 9	RHOSP 15		Supported for the autoscaling use case.
Ceilometer	RHOSP 4			Supported for collection of metrics and events for RHOSP in the autoscaling and Service Telemetry Framework (STF) use cases.
Collectd	RHOSP 11	RHOSP 17.1		Supported for collection of infrastructure metrics for STF.
Gnocchi	RHOSP 9	RHOSP 15		Supported for storage of metrics for the autoscaling use case.
Panko	RHOSP 11	RHOSP 12, not installed by default since RHOSP 14	RHOSP 17.0	

Component	Fully supported since	Deprecated in	Removed since	Note
QDR	RHOSP 13	RHOSP 17.1		Supported for transmission of metrics and events data from RHOSP to STF.

CHAPTER 2. MONITORING ARCHITECTURE

Monitoring tools use a client-server model with the client deployed onto the Red Hat OpenStack Platform overcloud nodes. The Rsyslog service provides client-side centralized logging (CL) and the collectd with enabled sensubility plugin provides client-side availability monitoring (AM).

2.1. CENTRALIZED LOGGING

In your Red Hat OpenStack environment, collecting the logs from all services in one central location simplifies debugging and administration. These logs come from the operating system, such as syslog and audit log files, infrastructure components such as RabbitMQ and MariaDB, and OpenStack services such as Identity, Compute, and others.

The centralized logging toolchain consists of the following components:

- Log Collection Agent (Rsyslog)
- Data Store (Elasticsearch)
- API/Presentation Layer (Kibana)

NOTE

Red Hat OpenStack Platform director does not deploy the server-side components for centralized logging. Red Hat does not support the server-side components, including the Elasticsearch database and Kibana.

2.2. AVAILABILITY MONITORING

With availability monitoring, you have one central place to monitor the high-level functionality of all components across your entire OpenStack environment.

The availability monitoring toolchain consists of several components:

- Monitoring Agent (collectd with enabled sensubility plugin)
- Monitoring Relay/Proxy (RabbitMQ)
- Monitoring Controller/Server (Sensu server)
- API/Presentation Layer (Uchiwa)

NOTE

Red Hat OpenStack Platform director does not deploy the server-side components for availability monitoring. Red Hat does not support the server-side components, including Uchiwa, Sensu Server, the Sensu API plus RabbitMQ, and a Redis instance running on a monitoring node.

The availability monitoring components and their interactions are laid out in the following diagrams:

NOTE

Items shown in blue denote Red Hat-supported components.

Figure 2.1. Availability monitoring architecture at a high level

Figure 2.2. Single-node deployment for Red Hat OpenStack Platform

Figure 2.3. HA deployment for Red Hat OpenStack Platform

OPENSTACK_435795_0117

CHAPTER 3. INSTALLING THE CLIENT-SIDE TOOLS

Before you deploy the overcloud, you need to determine the configuration settings to apply to each client. Copy the example environment files from the heat template collection and modify the files to suit your environment.

3.1. SETTING CENTRALIZED LOGGING CLIENT PARAMETERS

For more information, see [Enabling centralized logging with Elasticsearch](#) in the *Logging, Monitoring, and Troubleshooting* guide.

3.2. SETTING MONITORING CLIENT PARAMETERS

The monitoring solution collects system information periodically and provides a mechanism to store and monitor the values in a variety of ways using a data collecting agent. Red Hat supports collectd as a collection agent. Collectd-sensubility is an extension of collectd and communicates with Sensu server side through RabbitMQ. You can use Service Telemetry Framework (STF) to store the data, and in turn, monitor systems, find performance bottlenecks, and predict future system load. For more information about Service Telemetry Framework, see the [Service Telemetry Framework 1.3](#) guide.

To configure collectd and collectd-sensubility, complete the following steps:

1. Create **config.yaml** in your home directory, for example, **/home/templates/custom**, and configure the **MetricsQdrConnectors** parameter to point to STF server side:

```
MetricsQdrConnectors:
  - host: qdr-normal-sa-telemetry.apps.remote.tld
    port: 443
    role: inter-router
    sslProfile: sslProfile
    verifyHostname: false
MetricsQdrSSLProfiles:
  - name: sslProfile
```

2. In the **config.yaml** file, list the plug-ins you want to use under **CollectdExtraPlugins**. You can also provide parameters in the **ExtraConfig** section. By default, collectd comes with the **cpu**, **df**, **disk**, **hugepages**, **interface**, **load**, **memory**, **processes**, **tcpconns**, **unixsock**, and **uptime** plug-ins. You can add additional plug-ins using the **CollectdExtraPlugins** parameter. You can also provide additional configuration information for the **CollectdExtraPlugins** using the **ExtraConfig** option. For example, to enable the **virt** plug-in, and configure the connection string and the hostname format, use the following syntax:

```
parameter_defaults:
  CollectdExtraPlugins:
    - disk
    - df
    - virt

  ExtraConfig:
    collectd::plugin::virt::connection: "qemu:///system"
    collectd::plugin::virt::hostname_format: "hostname uuid"
```

**NOTE**

Do not remove the **unixsock** plug-in. Removal results in the permanent marking of the collectd container as unhealthy.

- Optional: To collect metric and event data through AMQ Interconnect, add the line **MetricsQdrExternalEndpoint: true** to the **config.yaml** file:

```
parameter_defaults:
  MetricsQdrExternalEndpoint: true
```

- To enable collectd-sensubility, add the following environment configuration to the **config.yaml** file:

```
parameter_defaults:
  CollectdEnableSensubility: true

  # Use this if there is restricted access for your checks by using the sudo command.
  # The rule will be created in /etc/sudoers.d for sensubility to enable it calling restricted
  # commands via sensubility executor.
  CollectdSensubilityExecSudoRule: "collectd ALL = NOPASSWD: <some command or ALL
  for all commands>"

  # Connection URL to Sensu server side for reporting check results.
  CollectdSensubilityConnection: "amqp://sensu:sensu@<sensu server side IP>:5672//sensu"

  # Interval in seconds for sending keepalive messages to Sensu server side.
  CollectdSensubilityKeepaliveInterval: 20

  # Path to temporary directory where the check scripts are created.
  CollectdSensubilityTmpDir: /var/tmp/collectd-sensubility-checks

  # Path to shell used for executing check scripts.
  CollectdSensubilityShellPath: /usr/bin/sh

  # To improve check execution rate use this parameter and value to change the number of
  # goroutines spawned for executing check scripts.
  CollectdSensubilityWorkerCount: 2

  # JSON-formatted definition of standalone checks to be scheduled on client side. If you
  # need to schedule checks
  # on overcloud nodes instead of Sensu server, use this parameter. Configuration is
  # compatible with Sensu check definition.
  # For more information, see https://docs.sensu.io/sensu-core/1.7/reference/checks/#check-
  # definition-specification
  # There are some configuration options which sensubility ignores such as: extension,
  # publish, cron, stdin, hooks.
  CollectdSensubilityChecks:
    example:
      command: "ping -c1 -W1 8.8.8.8"
      interval: 30

  # The following parameters are used to modify standard, standalone checks for monitoring
  # container health on overcloud nodes.
  # Do not modify these parameters.
```

```
# CollectdEnableContainerHealthCheck: true
# CollectdContainerHealthCheckCommand: <snip>
# CollectdContainerHealthCheckInterval: 10
# The Sensu server side event handler to use for events created by the container health
check.
# CollectdContainerHealthCheckHandlers:
# - handle-container-health-check
# CollectdContainerHealthCheckOccurrences: 3
# CollectdContainerHealthCheckRefresh: 90
```

5. Deploy the overcloud. Include **config.yaml**, **collectd-write-qdr.yaml**, and one of the **qdr-*.yaml** files in your overcloud deploy command:

```
$ openstack overcloud deploy
-e /home/templates/custom/config.yaml
-e tripleo-heat-templates/environments/metrics/collectd-write-qdr.yaml
-e tripleo-heat-templates/environments/metrics/qdr-form-controller-mesh.yaml
```

6. Optional: To enable overcloud RabbitMQ monitoring, include the **collectd-read-rabbitmq.yaml** file in the **overcloud deploy** command.

Additional resources

- For more information about the YAML files, see [Section 3.5, “YAML files”](#).
- For more information about collectd plug-ins, see [Section 3.4, “Collectd plug-in configurations”](#).
- For more information about Service Telemetry Framework, see the [Service Telemetry Framework 1.3](#) guide.

3.3. COLLECTING DATA THROUGH AMQ INTERCONNECT

To subscribe to the available AMQ Interconnect addresses for metric and event data consumption, create an environment file to expose AMQ Interconnect for client connections, and deploy the overcloud.

NOTE

The Service Telemetry Operator simplifies the deployment of all data ingestion and data storage components for single cloud deployments. To share the data storage domain with multiple clouds, see [Configuring multiple clouds](#) in the *Service Telemetry Framework 1.3* guide.

WARNING

It is not possible to switch between QDR mesh mode and QDR edge mode, as used by the Service Telemetry Framework (STF). Additionally, it is not possible to use QDR mesh mode if you enable data collection for STF.

Procedure

1. Log on to the Red Hat OpenStack Platform undercloud as the **stack** user.
2. Create a configuration file called **data-collection.yaml** in the **/home/stack** directory.
3. To enable external endpoints, add the **MetricsQdrExternalEndpoint: true** parameter to the **data-collection.yaml** file:

```
parameter_defaults:
  MetricsQdrExternalEndpoint: true
```

4. To enable collectd and AMQ Interconnect, add the following files to your Red Hat OpenStack Platform director deployment:
 - the **data-collection.yaml** environment file
 - the **qdr-form-controller-mesh.yaml** file that enables the client side AMQ Interconnect to connect to the external endpoints

```
openstack overcloud deploy <other arguments>
--templates /usr/share/openstack-tripleo-heat-templates \
--environment-file <...other-environment-files...> \
--environment-file /usr/share/openstack-tripleo-heat-
templates/environments/metrics/qdr-form-controller-mesh.yaml \
--environment-file /home/stack/data-collection.yaml
```

5. Optional: To collect Ceilometer and collectd events, include **ceilometer-write-qdr.yaml** and **collectd-write-qdr.yaml** file in your **overcloud deploy** command.
6. Deploy the overcloud.

Additional resources

- For more information about the YAML files, see [Section 3.5, “YAML files”](#).

3.4. COLLECTD PLUG-IN CONFIGURATIONS

There are many configuration possibilities of Red Hat OpenStack Platform director. You can configure multiple collectd plug-ins to suit your environment. Each documented plug-in has a description and example configuration. Some plug-ins have a table of metrics that you can query for from Grafana or Prometheus, and a list of options you can configure, if available.

Additional resources

- To view a complete list of collectd plugin options, see [collectd plugins](#) in the *Service Telemetry Framework* guide.

3.5. YAML FILES

You can include the following YAML files in your **overcloud deploy** command when you configure collectd:

- **collectd-read-rabbitmq.yaml**: Enables and configures **python-collect-rabbitmq** to monitor the overcloud RabbitMQ instance.
- **collectd-write-qdr.yaml**: Enables collectd to send telemetry and notification data through AMQ Interconnect.
- **qdr-edge-only.yaml**: Enables deployment of AMQ Interconnect. Each overcloud node has one local qdrouterd service running and operating in edge mode. For example, sending received data straight to defined **MetricsQdrConnectors**.
- **qdr-form-controller-mesh.yaml**: Enables deployment of AMQ Interconnect. Each overcloud node has one local qdrouterd service forming a mesh topology. For example, AMQ Interconnect routers on controllers operate in interior router mode, with connections to defined **MetricsQdrConnectors**, and AMQ Interconnect routers on other node types connect in edge mode to the interior routers running on the controllers.

Additional resources

For more information about configuring collectd, see [Section 3.2, “Setting monitoring client parameters”](#).
